

Computation Module for number of stages and minimum reflux using MATLAB

BY :AMIT KUMAR (19JE0115)

This problem statement has been taken

Ponchot Savarit Method: Distillation column, binary mixture

1000 kg/hr of a mixture containing 42 mole percent heptane and 58 mole percent ethyl benzene is to be fractionated to a distillate containing 97 mole percent heptane and a residue containing 99 mole percent ethyl benzene using a total condenser and feed at its saturated liquid condition. The enthalpy-concentration data for the heptane-ethyl benzene at 1 atm pressure are as follows:

xheptane	0	0.08	0.18	0.25	0.49	0.65	0.79	0.91	1.0
yheptane	0	0.28	0.43	0.51	0.73	0.83	0.90	0.96	1.0
Hl (kJ/kmol) x 10 ⁻³	24.3	24.1	23.2	22.8	22.05	21.75	21.7	21.6	21.4
Hv (kJ/kmol) x 10 ⁻³	61.2	59.6	58.5	58.1	56.5	55.2	54.4	53.8	53.3

GOVERNING EQUATIONS.

- **Variables:**

- Liquid flow rate across plates : L_n
- Vapor flow rate across plates : V_{n+1}
- Mole ratio in vapor and liquid phase of each tray : y_{n+1} , x_n
- Molar enthalpy of vapor and liquid phase across each tray : $H_{V_{n+1}}$, H_{L_n} .

- **Constants:**

- Reflux ratio (R) , Top and Lower product flow rate (D & W) and their respective mole ratios(x_d , x_w) , Heat Duties (Qb,Qd), Feed Flow rate (F, z_f) .

RECTIFYING SECTION:

$$\mathbf{V}_{n+1} = \mathbf{L}_n + \mathbf{D}$$

- $\mathbf{V}_{n+1} * \mathbf{y}_{n+1} = \mathbf{L}_n * \mathbf{x}_n + \mathbf{D} * \mathbf{x}_d$
- $\mathbf{V}_{n+1} * \mathbf{H}_{\mathbf{V}_{n+1}} = \mathbf{L}_n * \mathbf{H}_{\mathbf{L}_n} + \mathbf{Qd}'$
- $\mathbf{y} = \text{interp1}(\mathbf{x}_e, \mathbf{y}_e, \mathbf{x}_n)$
- $\mathbf{H}_{\mathbf{L}_n} = \text{interp1}(\mathbf{x}_e, \mathbf{H}_l, \mathbf{x}_n)$
- $\mathbf{H}_{\mathbf{V}_{n+1}} = \text{interp1}(\mathbf{y}_e, \mathbf{H}_v, \mathbf{y}_{n+1})$

STRIPPING SECTION:

$$V_{m+1} = L_m - W$$

- $V_{m+1} * y_{m+1} = L_m * x_m - W * x_w$
- $V_{m+1} * H_{V_{m+1}} = L_m * H_{L_m} - Qc'$
- $y = \text{interpl}(x_e, y_e, x_m)$
- $H_{L_m} = \text{interpl}(x_e, H_l, x_m)$
- $H_{V_{m+1}} = \text{interpl}(y_e, H_v, y_{m+1})$

Flowchart for graphical Ponchon savarit:

Enthalpy concentration H_v vs y and H_l vs x are drawn.

Energy and Material balance we get points $D_{\text{dash}}, S_{\text{dash}}$.

From the proof of collinearity we get that $D_{\text{dash}}, (H_{ln}, x_n), (H_{vn+1}, Y_{n+1})$ are on the same line.

Joining the points Q_{dash} and D we get Y_l .

From the Y_1 using equilibrium data we get x_1 .

From collinearity principle joining point L_1 and D_{dash} we get Y_2 .

Repeat till it crosses the feed line and rectifying section is done.

Joining the W and S_{dash} we get y_n and using equilibrium data we get x_n , same repeated as rectifying section.

Flowchart for Numerical ponchon savarit:

Calculate $y_1, H_{I0}, H_{v1}, L_0, V_1$ from x_d for the first tray using fsolve.

Calculate x_1 from y_1 by interpolating from the equilibrium curve.

Use this x_1 , to solve for $y_2, H_{I1}, H_{v2}, L_1, V_2$ using Material balance, component balance, energy balance, H_v-y , H_I-x equations.

Again we get x_2 by interpolation from equilibrium curve.
We go on doing like this till the feed tray.

When we go past the feed tray, the governing equations will change but the procedure will remain the same.

The main problem we faced is when we tried to write the equations for a particular tray. the material balance, component balance, energy balance equations required y_{n+1} and x_n whereas the equilibrium relation is valid between y_n and x_n . We tackled the problem by using a global variable i.e. we are sending x_n from the previous iteration to be used in the current iteration in equilibrium relation

Steps Involved -

1. Using the classic Ponchon-Savarit method we created the heat map .
2. Finding out the number of the stages and feed plate tray from the classic Ponchon-Savarit.
3. Based on the number of stages and the feed plate entry we write the equations for each stage. For each stage we know 'x' value (which we get from previous stage or for 1st stage it will be x_d) and then there are 5 variables (unknowns) y , H_l , H_v , L , V which will be solved by `fsolve`. Then we can find x for next stage from equilibrium curve using y from current stage.
4. Writing the material balance, component balance, energy balance, H_L - x curve, H_v - y curve and x - y curve we get the required equations to solve the variables we have.
5. At each stage using `fsolve` to solve the set of the equations we get 5 variables solution using equilibrium curve function we get x using y .

6. Same process is repeated till we reach the feed plate, till this step we use rectifying section equations.

7. After crossing the feed plate now the same process is repeated for stripping section using stripping section equations.

8. After collecting values of x , y , H_L , H_v , V , L at each stage we draw a heat map and compare it with the heat map that we got using simple Ponchon-Savarit.
